

A teratologic case in *Oenopiella punctaria* (Stål, 1859) (Heteroptera: Pentatomidae: Pentatominae: Carpocorini) from the Aisén region (Chile)

Un caso teratológico en *Oenopiella punctaria* (Stål, 1859) (Heteroptera: Pentatomidae: Pentatominae: Carpocorini) de la región de Aisén (Chile)

Eduardo I. Faúndez^{1,2} & Alfredo Lüer³

Abstract

A teratological case is described in one specimen of *Oenopiella punctaria* (Stål, 1859) from Aisén Region, Chile. Malformations belongs to the group of the hemiteries (a pronotal dysplasia), and ectromelies (a right antennal atrophy). Possible causes of the teratological case are discussed.

Key words:

Heteroptera, Pentatomidae, Pentatominae, Carpocorini, teratology, Chile.

Resumen

Se describe un caso teratológico en un ejemplar de *Oenopiella punctaria* (Stål, 1859) de la Región de Aisén, Chile. Las malformaciones corresponden al grupo de las hemiterias (una displasia pronotal) y ectromelias (una atrofia antenal derecha). Se discuten las posibles causas de la teratosis.

Palabras clave:

Heteroptera, Pentatomidae, Pentatominae, Carpocorini, teratología, Chile.

INTRODUCTION

The teratosis are singular facts which occur on individuals, influencing on its ontogeny. However these facts can last on the time, and display on the phylogeny of a determined lineage (Ortuño & Ramos, 2008).

At world level, the major works about teratology on Hemipterans were undertaken by Balazuc (1951) and Šlusák & Sthelik (1977, 1978,

1979, 1980, 1982).

In Chile this discipline was highly fructiferous in the first half of the 20th century (Pérez D'Angello, 1967). However, according Pérez D'Angello (1967), the majority of the published reports from Chile belong to Coleoptera. Faúndez (2007) wrote that this tendency continue at the present years. In the country, for Heteroptera, there is just one case reported, in one species of Acanthosomatidae (Faúndez & Carvajal, 2011).

Recent collections in the Aisén Region of Chile, allowed us to recognize a teratological case in *Oenopiella punctaria* (Stål, 1859) including hemiteries and ectromelies. *Oenopiella punctaria* is one of the 27 species of Pentatominae (Carpocorini) recorded from Chile (Faúndez & Rider, 2014a), and it is also distributed in Argentina, Brazil and Uruguay (Fernández-Aldea *et al.* 2014). No further data is known about *O. punctaria* (e.g. bionomics, immature stages); like several other Chilean species of Carpocorini (Faúndez & Rider, 2014b).

Among the teratosis, the ectromelies are defined as the lack or diminution of an appendix (Dallas, 1926). On the other hand the hemiteries are defined as general deformations and/or

malformations (Dallas, 1926).

MATERIALS AND METHODS

For terminology and classification we follow Dallas (1926), Balazuc (1951) and Šlusák & Sthelik (1978). The specimen was prepared for dissection on barber's fluid for 12 hours. Photos were taken with a digital camera adapted to a stereoscopic microscope.

Material examined: Chile, Aisén Region, Coihaique, Balmaceda, 45°42'25"S-71°41'33"W, 10-II-2013, Leg. A. Lüer, 525 m s.n.m., 1♀ (Dissected,

in alcohol on E. Faúndez coll.), under shrubs of typical patagonic steppe of Aisén (*sensu* Gajado, 1994).

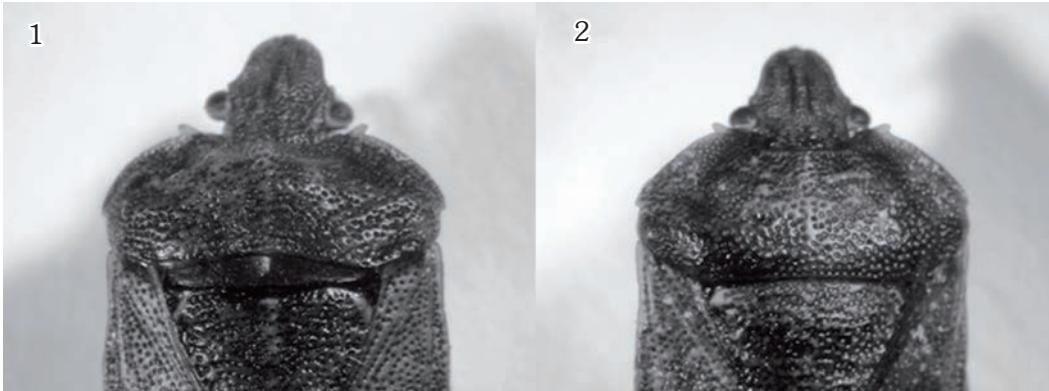

RESULTS

Pronotal dysplasia (Figs. 1, 3, 5, 7)

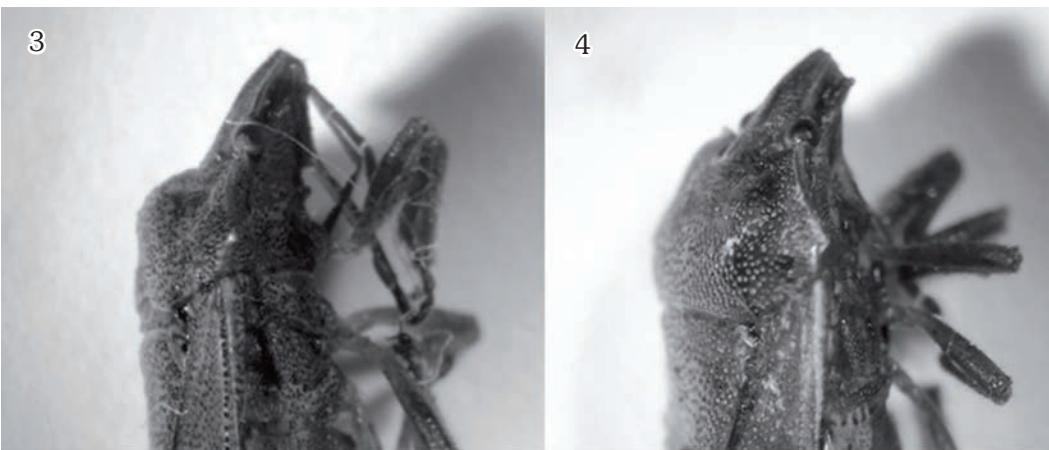

Description: The pronotum has an enlarged median bump (Figs. 1, 3), which is absent in normal specimens. In lateral view it looks very convex compared to a normal specimen (Figs. 2, 4). This malformation produces stretching and contracting

Table I. measures (in millimeters) of the antennae of the teratological specimen of *O. punctaria*

Antennomere	I	II	III	IV	V
Right antenna	0.42	0.51	0.57	0.71	absent
Left antenna	0.42	0.51	0.68	0.59	0.95

of the tegument; leaving uncovered the anterior portion of the pterothorax (Fig. 7). Internally we found a rounded fatty tumor. After its removal, we found that the transverse muscles are attached more distally (Fig. 5) than in a normal specimen (Fig. 6)

Right antennal atrophy (Fig. 8)

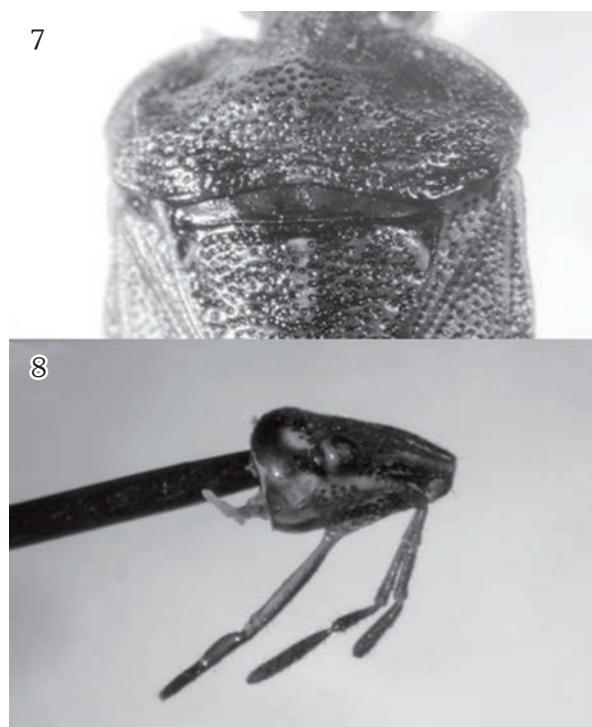

Description: The right antenna has a multi-segment atrophy; the left antenna is normal (Fig. 8). The 5th antennomere is absent. The 4th antennomere is larger than the 4th antennomere in the left antenna. The 3rd antennomere is shorter than the 3rd antennomere in the left antenna. 1st and 2nd antennomeres are normal.

DISCUSSION AND CONCLUSIONS

The dysplasias are a type of malformation relatively common in insects; however these are hard to study, because of its different possible origins (Balazuc, 1951). The antennal malformations are the most common in the Heteropterans (Costas

et al. 1992). Many of these malformations are originated because of injuries produced on immature stages, and posterior regenerations (Štusak & Sthelik, 1978).

We believe possible that the malformations here described have in part exogenous origin (i.e. missing an antennomere during moulting and/or because a trauma); which subsequently, during the ontogeny, produced another endogenous teratosis (i.e. dysplasia, change in the relative length of antennomeres).

This case is also interesting because of the low number of teratosis reported for Heteropterans including two types of malformations.
