

# A teratological case in the family Idiostolidae (Hemiptera: Heteroptera: Idiostoloidea)

Un caso teratológico en la familia Idiostolidae  
(Hemiptera: Heteroptera: Idiostoloidea)

Mariom A. Carvajal<sup>1,2</sup> & Eduardo I. Faúndez<sup>1,2</sup>

## Abstract

A teratosis is described for the first time in the family Idiostolidae; more specifically a female of *Idiostolus insularis* (Berg, 1881). The specimen was collected in Punta Arenas, Magallanes Region, Chile. The malformation is classified as an oligomeromy in the right antennae, and it is believed that it was caused probably due regeneration after an injury during an early instar.

## Key words:

*Idiostolus insularis*, Teratology, antennal malformation, South America.

## Resumen

Se describe por primera vez una teratosis en la familia Idiostolidae, específicamente en una hembra de *Idiostolus insularis* (Berg, 1881) recolectada en Punta Arenas, Región de Magallanes, Chile. La malformación se clasifica como una oligomería en la antena derecha, y se cree que fue causada por alguna herida o trauma durante algún instar previo.

## Palabras clave:

*Idiostolus insularis*, Teratología, malformación antenal, Sudamérica.

## INTRODUCTION

The Idiostolidae Scudder, 1962, commonly known as transantarctic bugs, are a Heteropteran family which comprises five species in three genera. Idiostolids inhabit the southern hemisphere, having a classical Gondwanian distribution (Schaefer & Wilcox, 1969). Little is known about the biology

of transantarctic bugs (Schaefer & Wilcox, 1969), which are believed to be inhabitants of mosses and litter associated with *Nothofagus* Blume (Nothofagaceae) forests (Schuh & Slater, 1995). In South America, Idiostolidae is represented by two species, both on the genus *Idiostolus* (Faúndez et al, 2014). *Idiostolus insularis* (Berg, 1881) is the widest distributed species of this genus. It is present in Southern Chile and Argentinean Patagonia, reaching latitudes where the weather conditions are unfavorable for most Heteropterans (Carvajal & Faúndez, 2011).

Teratology is the study of malformations and abnormalities; in a more colloquial language, it is known as the study of the monsters and semimonsters (Dallas, 1926; Perez D'Angello, 1967). Teratosis are singular facts which occur on individuals, influencing on its ontogeny. However, in some cases these facts can last on the time, and on the phylogeny of a determined lineage (Ortuño & Ramos, 2008).

For the Heteroptera, the major contributions on this field are those of Balazuc (1951) and Šlusák & Stelišk (1977, 1978, 1979, 1980, 1982); however, there are few reports regarding Chilean Heteropterans (Faúndez & Rocca, 2016).

<sup>2</sup> Departamento de Zoología Médica, Centro de Estudios en Biodiversidad (CEBCh), Magallanes, 1979, Osorno, Chile.

The purpose of this contribution is to describe a teratological specimen of *Idiostolus insularis* from the Magallanes Region.

## MATERIALS AND METHODS

In terminology and teratological classification we follow Balazuc (1951) and Šlusak & Stelík (1978). Photos were taken with a digital camera adapted to a stereoscopic microscope. All measurements are expressed in millimeters.

## RESULTS

Oligomery in right antenna of *Idiostolus insularis* (Berg, 1881) (Figures 1-3)

Fig. 1. Teratological specimen of *Idiostolus insularis*, left and right antennae, dorsal view; Fig. 2. Teratological specimen of *Idiostolus insularis*, detailed view of left and right first antennomere.

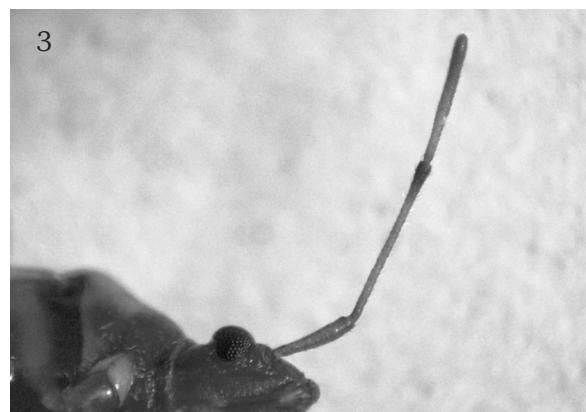

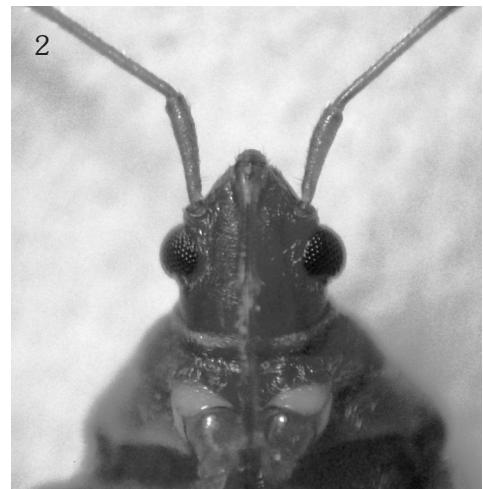

Fig. 3. Teratological specimen of *Idiostolus insularis*, detail of right antenna, ventral view.

In the present case the left antenna of the adult specimen is normal, having 4 segments (Table I; Fig. 1). On the other hand, the right antenna has only 3 segments, which have different size proportions compared to the first 3 segments in the normal antenna (Fig. 3; Table I). In the teratologic antenna the first antennomere is shorter and thicker than the normal antenna (Fig. 2); the second antennomere, although it has the same color pattern and shape (Fig. 2), is longer than in the normal one (Fig. 3). The third antennomere in the right antenna is longer than its left counterpart (Table I), and it has similar shape and color pattern as the fourth antennomere in the normal antenna (Figs. 1, 3).

Material examined: Chile, Magallanes,

20-I-2011, Jardín Botánico Carl Skottsberg, Instituto de la Patagonia, Carvajal & Faúndez leg, 1♀, on *Nothofagus antarctica* (Mirb.) Oerst (Nothofagaceae). (Deposited in the Heteroptera Reference Collection of the Centro de Estudios en Biodiversidad, HRCC).

## DISCUSSION AND CONCLUSIONS

The teratologic specimen in this work presents an oligomery, where the fourth segment of the right antenna has been lost. Oligomeries as defined by Šlusak & Stelík (1978) are the reduction in the number of segments; and usually are due to injury in early life stages. For this

Table I. Antennal measurements of the *Idiostolus insularis* teratological specimen.

Antennomere	I	II	III	IV	Total
Left antenna	0.71	1.05	0.96	1.14	3.86
Right antenna	0.59	1.33	1.06	-	2.98

case, the loss of the fourth segment could be due to injury during the molting process, giving place for regeneration before reaching the adult stage. According to Štusak & Stelihk (1978), the generation of bigger or more developed segments following the malformation, like in the present case, is influenced by the loss of the segment itself, as a way to compensate the losing. On this way, it is also common that the terminal regenerated segment acquires characteristics of the last segment to avoid missing some sensorial properties of the last antennomere (Štusak & Sthelik, 1978); which appeared to happen on this case (Fig. 3). Furthermore, this anomaly can also be classified as a simple oligomery, where no anarthrogenesis can be observed, and acquirement of function by the substituting segments is possible. This kind of teratosis have been observed for other heteropterans (Stusak & Sthelik, 1978; Balazuc, 1951); especially in Lygaeidae and affine groups, where antennal teratosis are the most common (Costas *et al.*, 1992). However, no previous cases are known for the family Idiostolidae. In Chile Heteropteran antennal malformations have been described for an Acanthosomatid (Faúndez & Carvajal, 2011); a Pentatomid (Faúndez & Lüer, 2015); and a Lygaeid (Faúndez & Rocca, 2016), becoming this report the fourth case of an antennal teratosis on a Chilean Heteropteran.
